### 6.1.1 Detailed Description

**template<typename E> class decaf::util::AbstractCollection< E >**

This class provides a skeletal implementation of the **Collection** (p. 1216) interface, to minimize the effort required to implement this interface. To implement an unmodifiable collection, the programmer needs only to extend this class and provide implementations for the iterator and size methods. (The iterator returned by the iterator method must implement hasNext and next.)

To implement a modifiable collection, the programmer must additionally override this class's add method (which otherwise throws an UnsupportedOperationException), and the iterator returned by the iterator method must additionally implement its remove method.

The programmer should generally provide a void (no argument) and **Collection** (p. 1216) constructor, as per the recommendation in the **Collection** (p. 1216) interface specification.

The documentation for each non-abstract method in this class describes its implementation in detail. Each of these methods may be overridden if the collection being implemented admits a more efficient implementation.

## 6.1.3 Member Function Documentation

6.1.3.1 `template<typename E> virtual bool decaf::util::AbstractCollection<  
E >::add ( const E &value DECAF_UNUSED ) throw (  
lang::exceptions::UnsupportedOperationException,  
lang::exceptions::IllegalArgumentException,  
lang::exceptions::IllegalStateException ) [inline, virtual]`

Ensures that this collection contains the specified element (optional operation).

Returns true if this collection changed as a result of the call. (Returns false if this collection does not permit duplicates and already contains the specified element.)

Collections that support this operation may place limitations on what elements may be added to this collection. **Collection** (p. 1216) classes should clearly specify in their documentation any restrictions on what elements may be added.

If a collection refuses to add a particular element for any reason other than that it already contains the element, it must throw an exception (rather than returning false). This preserves the invariant that a collection always contains the specified element after this call returns.

This implementation always throws an UnsupportedOperationException.

### Parameters

<i>value</i>	- The element that must be ensured to be in this collection.
--------------	--

### Returns

true if the collection was changed as a result of this call.

### Exceptions

<i>UnsupportedOperationException</i>	if the add operation is not supported by this collection
--------------------------------------	--

<i>IllegalArgumentException</i>	if some property of the element prevents it from being added to this collection
<i>IllegalStateException</i>	if the element cannot be added at this time due to insertion restrictions

Referenced by decaf::util::AbstractCollection< cms::Connection \* >::addAll(), decaf::util::AbstractCollection< cms::Connection \* >::copy(), and decaf::util::AbstractCollection< cms::Connection \* >::operator=().

**6.1.3.2** `template<typename E> virtual bool decaf::util::AbstractCollection< E >::addAll ( const Collection< E > & collection ) throw ( lang::exceptions::UnsupportedOperationException, lang::exceptions::IllegalArgumentException, lang::exceptions::IllegalStateException ) [inline, virtual]`

Adds all of the elements in the specified collection to this collection (optional operation).

The behavior of this operation is undefined if the specified collection is modified while the operation is in progress. (This implies that the behavior of this call is undefined if the specified collection is this collection, and this collection is nonempty.)

This implementation iterates over the specified collection, and adds each object returned by the iterator to this collection, in turn.

Note that this implementation will throw an UnsupportedOperationException unless add is overridden (assuming the specified collection is non-empty).

#### Parameters

<i>collection</i>	- The <b>Collection</b> (p. 1216) whose elements are to be added to this <b>Collection</b> (p. 1216).
-------------------	---

#### Returns

true if the collection was changed as a result of this call.

#### Exceptions

<i>UnsupportedOperationException</i>	if the addAll operation is not supported by this collection
<i>IllegalArgumentException</i>	if some property of the element prevents it from being added to this collection
<i>IllegalStateException</i>	if the element cannot be added at this time due to insertion restrictions

Implements **decaf::util::Collection< E >** (p. 1219).

Reimplemented in **decaf::util::AbstractQueue< E >** (p. 177).

```
6.1.3.3 template<typename E> virtual void decaf::util::AbstractCollection< E >::clear (
    ) throw ( lang::exceptions::UnsupportedOperationException ) [inline,
    virtual]
```

Removes all of the elements from this collection (optional operation).

The collection will be empty after this method returns.

This implementation iterates over this collection, removing each element using the **Iterator.remove** (p. 2223) operation. Most implementations will probably choose to override this method for efficiency.

Note that this implementation will throw an `UnsupportedOperationException` if the iterator returned by this collection's iterator method does not implement the remove method and this collection is non-empty.

### Exceptions

<i>UnsupportedOperationException</i>	if the clear operation is not supported by this collection
--------------------------------------	--

This implementation iterates over this collection, checking each element returned by the iterator in turn to see if it's contained in the specified collection. If it's so contained, it's removed from this collection with the iterator's remove method.

Note that this implementation will throw an `UnsupportedOperationException` if the iterator returned by the iterator method does not implement the remove method and this collection contains one or more elements in common with the specified collection.

**Parameters**

In other words, removes from this collection all of its elements that are not contained in the specified collection.

This implementation iterates over this collection, checking each element returned by the iterator in turn to see if it's contained in the specified collection. If it's not so contained, it's removed from this collection with the iterator's remove method.

Note that this implementation will throw an `UnsupportedOperationException` if the iterator returned by the iterator method does not implement the remove method and this collection contains one or more elements not present in the specified collection.

#### Parameters

```

Waits on a signal from this object, which is generated by a call to Notify.

Must have this object locked before calling. This wait will timeout after the specified time interval. This method is similar to the one argument wait function except that it add a finer grained control over the amount of time that it waits by adding in the additional nanosecond argument.

### 6.2.1 Detailed Description

`template<typename E> class decaf::util::AbstractList< E >`

This class provides a skeletal implementation of the **List** (p. 2409) interface to minimize the effort required to implement this interface backed by a "random access" data store (such as an array). For sequential access data (such as a linked list), **AbstractSequentialList** (p. 179) should be used in preference to this class.

To implement an unmodifiable list, the programmer needs only to extend this class and provide implementations for the `get(int)` and `size()` (p. 1226) methods.

To implement a modifiable list, the programmer must additionally override the `set(int, E)` method (which otherwise throws an `UnsupportedOperationException`). If the list is variable-size the programmer must additionally override the `add(int, E)` and `remove(int)` methods.

The programmer should generally provide a void (no argument) and collection constructor, as per the recommendation in the **Collection** (p. 1216) interface specification.

Unlike the other abstract collection implementations, the programmer does not have to provide an iterator implementation; the iterator and list iterator are implemented by this class, on top of the "random access" methods: `get(int)`, `set(int, E)`, `add(int, E)` and `remove(int)`.

The documentation for each non-abstract method in this class describes its implementation in detail. Each of these methods may be overridden if the collection being implemented admits a more efficient implementation.

#### 6.3.1 Detailed Description

```
template<typename K, typename V, typename COMPARATOR> class decaf::util::AbstractMap<  
K, V, COMPARATOR >
```

This class provides a skeletal implementation of the **Map** (p. 2538) interface, to minimize the effort required to implement this interface. To implement an unmodifiable map, the programmer needs only to extend this class and provide an implementation for the `entrySet` method, which returns a set-view of the map's mappings. Typically, the returned set will, in turn, be implemented atop **AbstractSet** (p. 180). This set should not support the `add` or `remove` methods, and its iterator should not support the `remove` method.

To implement a modifiable map, the programmer must additionally override this class's `put` method (which otherwise throws an `UnsupportedOperationException`), and the iterator returned by `entrySet().iterator()` must additionally implement its `remove` method.

The programmer should generally provide a void (no argument) and map constructor, as per the recommendation in the **Map** (p. 2538) interface specification.

The documentation for each non-abstract method in this class describes its implementation in detail. Each of these methods may be overridden if the map being implemented admits a more efficient implementation.

### 6.4.1 Detailed Description

template<typename E> class decaf::util::AbstractQueue< E >

This class provides skeletal implementations of some **Queue** (p. 3239) operations. Methods add, remove, and element are based on offer, poll, and peek, respectively.

A **Queue** (p. 3239) implementation that extends this class must minimally define a method **Queue** (p. 3239). **offer(E)** which does not permit insertion of null elements, along with methods **Queue** (p. 3239). **peek()** (p. 3242), **Queue.poll()** (p. 3242), **Collection.size()** (p. 1226), and a **Collection.iterator()** (p. 2221) supporting **Iterator.remove()** (p. 2223). Typically, additional methods will be overridden as well. If these requirements cannot be met, consider instead subclassing **AbstractCollection** (p. 159).

Inserts the specified element into this queue if it is possible to do so immediately without violating capacity restrictions, returning true upon success and throwing an IllegalStateException if no space is currently available.

This implementation returns true if offer succeeds, else throws an IllegalStateException.

#### Parameters

<i>value</i>	- the element to offer to the <b>Queue</b> (p. 3239).
--------------	---

#### Returns

true if the add succeeds.

#### Exceptions

<i>IllegalArgumentException</i>	if the element cannot be added.

Adds all the elements of a collection to the queue.

If the collection is the queue itself, then an `IllegalArgumentException` will be thrown out. If during the process, some runtime exception is thrown out, then part of the elements in the collection that have successfully added will remain in the queue.

The result of the method is undefined if the collection is modified during the process of the method.

#### Parameters

#### 6.5.1 Detailed Description

```
template<typename E> class decaf::util::AbstractSequentialList< E >
```

This class provides a skeletal implementation of the **List** (p. 2409) interface to minimize the effort required to implement this interface backed by a "sequential access" data store (such as a linked list). For random access data (such as an array), **AbstractList** (p. 173) should be used in preference to this class.

This class is the opposite of the **AbstractList** (p. 173) class in the sense that it implements the "random access" methods (`get(int index)`, `set(int index, E element)`, `add(int index, E element)` and `remove(int index)`) on top of the list's list iterator, instead of the other way around.

To implement a list the programmer needs only to extend this class and provide implementations for the `listIterator` and `size` methods. For an unmodifiable list, the programmer need only implement the list iterator's `hasNext`, `next`, `hasPrevious`, `previous` and `index` methods.

For a modifiable list the programmer should additionally implement the list iterator's `set` method. For a variable-size list the programmer should additionally implement the list iterator's `remove` and `add` methods.

The programmer should generally provide a void (no argument) and collection constructor, as per the recommendation in the **Collection** (p. 1216) interface specification.

### 6.6.1 Detailed Description

`template<typename E> class decaf::util::AbstractSet< E >`

This class provides a skeletal implementation of the **Set** (p. 3538) interface to minimize the effort required to implement this interface. The process of implementing a set by extending this class is identical to that of implementing a **Collection** (p. 1216) by extending **AbstractCollection** (p. 159), except that all of the methods and constructors in subclasses of this class must obey the additional constraints imposed by the **Set** (p. 3538) interface (for instance, the add method must not permit addition of multiple instances of an object to a set).

6.6.3.1 `template<typename E> virtual bool decaf::util::AbstractSet< E >::removeAll ( const Collection< E > & collection ) throw ( lang::exceptions::UnsupportedOperationException, lang::exceptions::IllegalArgumentException ) [inline, virtual]`

Removes from this set all of its elements that are contained in the specified collection (optional operation).

If the specified collection is also a set, this operation effectively modifies this set so that its value is the asymmetric set difference of the two sets.

This implementation determines which is the smaller of this set and the specified collection, by invoking the size method on each. If this set has fewer elements, then the implementation iterates over this set, checking each element returned by the iterator in turn to see if it is contained in the specified collection. If it is so contained, it is removed from this set with the iterator's remove method. If the specified collection has fewer elements, then the implementation iterates over the specified collection, removing from this set each element returned by the iterator, using this set's remove method.

Note that this implementation will throw an `UnsupportedOperationException` if the iterator returned by the iterator method does not implement the remove method.

### Parameters

- Mark all messages that might have been delivered but not acknowledged as "re-delivered"

- Restart the delivery sequence including all unacknowledged messages that had been previously delivered. Redelivered messages do not have to be delivered in exactly their original delivery order.

Reads a portion of the Stream message stream.

If the length of array value is less than the number of bytes remaining to be read from the stream, the array should be filled. A subsequent call reads the next increment, and so on.

If the number of bytes remaining in the stream is less than the length of array value, the bytes should be read into the array. The return value of the total number of bytes read will be less than the length of the array, indicating that there are no more bytes left to be read from the stream. The next read of the stream returns -1.

If length is negative, or length is greater than the length of the array value, then an CMSException is thrown. No bytes will be read from the stream for this exception case.

#### Parameters

<i>buffer</i>	the buffer into which the data is read
<i>length</i>	the number of bytes to read; must be less than or equal to value.length

If the number of bytes remaining in the stream is less than the length of vector value, the bytes should be read into the vector. The return value of the total number of bytes read will be less than the length of the vector, indicating that there are no more bytes left to be read from the stream. The next read of the stream returns -1.

6.78.2.1 `virtual ActiveMQTempDestination* activemq::commands::ActiveMQTempDestination::cloneDataStructure ( ) const [inline, virtual]`

Clone this object and return a new instance that the caller now owns, this will be an exact copy of this one.

### Returns

new copy of this object.

### 6.113.1 Detailed Description

Transaction Management class, hold messages that are to be redelivered upon a request to roll-back. The Transaction represents an always running transaction, when it is committed or rolled back it silently creates a new transaction for the next set of messages. The only way to permanently end this transaction is to delete it.

## 6.115 decaf::lang::Appendable Class Reference

- virtual `Appendable & append(const CharSequence *csq, int start, int end)=0` throw ( decaf::lang::Exception )  
*Appends a subsequence of the specified character sequence to this **Appendable** (p. 733).*

### 6.115.1 Detailed Description

An object to which char sequences and values can be appended. The **Appendable** (p. 733) interface must be implemented by any class whose instances are intended to receive formatted output from a Formatter.

TODO The characters to be appended should be valid Unicode characters as described in Unicode **Character** (p. 1126) Representation. Note that supplementary characters may be composed of multiple 16-bit char values.

Appendables are not necessarily safe for multithreaded access. **Thread** (p. 3876) safety is the responsibility of classes that extend and implement this interface.

Since this interface may be implemented by existing classes with different styles of error handling there is no guarantee that errors will be propagated to the invoker.
